1. Femtosecond PW laser system
2. **Relativistic Laser Science**
 - A. Laser electron acceleration
 - B. High energy proton generation
 - C. Relativistic harmonic generation

● *Exploration of Relativistic Laser-Matter Interactions*

- **Basic Relativistic LMI Physics**

Relativistic self-focusing, relativistic flying mirror, relativistic transparency
Giga-Gauss DC Magnetic Field Generation

- **Mono-energetic Particle Acceleration**

- | Mono-energetic electron acceleration by LWFA
- | High-energy proton generation by TNSA and RPA

- **High Energy Photon Generation**

γ -ray generation through Betatron radiation and Inverse Compton Scattering (ICS)

● *Attosecond Science*

- **Attosecond light sources**

- | High harmonic generation from gaseous atoms
- | High harmonic generation from solid materials

- **Ultrafast atomic and molecular dynamics**

Atomic field strength: $E_B = \frac{e}{r_B^2} \approx 5.1 \times 10^9 \text{ V/cm}$; $I_B = \frac{cE_B^2}{8\pi} \approx 3.5 \times 10^{16} \text{ W/cm}^2$

$$a_0 \equiv \frac{v_{NR}}{c} = \frac{eE_0}{m_e \omega_0 c} = \frac{eA_0}{m_e c^2} = \frac{\text{speed of nonrelativistically oscillating electron}}{\text{speed of light}}$$

When $a_0 = 1$, $v = 0.75c$. For $a_0 > 1$, relativistic.

Intensity for relativistic electron:
(Relativistic regime)

$$I_{Re} \approx \frac{1.4 \times 10^{18}}{(\lambda^2)_{\mu m}} a_0^2 \text{ W/cm}^2$$

For $a_0 = \frac{M_p}{m_e} = 1800$, ultra-relativistic.

Intensity for relativistic proton:
(Ultra-relativistic regime)

$$I_{Rp} \approx \frac{4.5 \times 10^{24}}{(\lambda^2)_{\mu m}} \text{ W/cm}^2$$

Laser Wake Field Electron Acceleration

Underomotive force
intense laser pulse
the original position

- Electron plasma wave created
- Acceleration of an injected electron bunch by the plasma wave

Huge acceleration field of LWFA > 100 GeV/m

**Plasma wave by a laser pulse
~ Waves by a ship in sea**

**Acceleration by plasma wave
~ Surfing to the wave in sea**

CRLS Multi-GeV electron Beam using PW Laser Pulses

Two-stage electron acceleration

Self-Injection with Long Depletion and Dephasing Lengths

- Pumping energy 22–25 J on target with 60 fs pulse duration
- 4 mm, 10 mm, elongated supersonic He gas jet
- Laser Intensity = $3 \times 10^{19} \text{ W/cm}^2$ ($a_0 = 3.7$)

Electron energy spectrum

Generation of Energetic Protons

Acceleration mechanism	laser	Target thickness	Characteristics	Energy scaling
TNSA (Target normal sheath acceleration)	$I > 10^{18} \text{ W/cm}^2$ Linear pol.	$\sim \mu\text{m}$	Broad spectrum Thermal electrons	$E_{ion} \propto I^{1/2}$
RPA (Radiation pressure acceleration)	$I > 10^{20} \text{ W/cm}^2$ Linear pol. Circular pol.	$\sim \text{nm}$	Quasi-monoenergetic, collective electrons	$E_{ion} \propto I$

Laser, not penetrating the target, heats electrons, which drag protons after penetrating the target.

Laser pulse pushes electrons as a whole, which drag the protons.

CRLS PW Target chamber for proton experiment

Target: polymer, DLC, Al
Thickness: μm to 10 nm
Intensity range w/ PM:
 $0.5 \times 10^{20} \text{ W/cm}^2 - 3.3 \times 10^{20} \text{ W/cm}^2$
Linear pol.: s-pol on target
Incidence angle: 7 deg. to the normal

Target and Thomson parabola

Temporal profiles measured with a third-order cross correlator.

Contrast 10^{-8} (w/o PM) $\rightarrow$ 10^{-12} (w/ PM)
Contrast enhancement: 10^4

Proton and C^{6+} measured with Thomson parabola

Energy spectra of protons and carbon ions obtained from a **10-nm-thick polymer target** irradiated with $I = 3.3 \times 10^{20} \text{ W/cm}^2$.

The proton energy of 45 MeV is highest among those obtained with high-power Ti:Sapphire lasers.

Intensity scaling from $\sim I^{1/2}$ to $\sim I \Rightarrow$ Transition from TNSA to RPA

Proton

45 MeV @ $3.3 \times 10^{20} \text{ W/cm}^2$
(linear polarization)

C⁶⁺ ion

165 MeV @ $3.3 \times 10^{20} \text{ W/cm}^2$
(linear polarization)

The feasibility of proton & heavy ion therapy using a table top laser facility

Proton/ion acceleration
using cyclotron/synchrotron

Particle acceleration
using a table top laser

Proton beam therapy has a physical advantage over gamma ray and x-rays when it comes to dosage deposition in healthy tissues. The energy can be very precisely controlled to place the Bragg peak within a tumor or other tissues targeted to receive the radiation dose. Because the energy deposition of protons is localized, healthy tissues beyond the target receive very little radiation.

● *Exploration of Attosecond Science*

- **Development of Attosecond (as) Photon Sources**

High-harmonic generation (HHG) from gaseous targets – He, Ne, Ar, Xe
HHG from solid targets in the relativistic regime

- **Characterization of Attosecond Pulses**

Autocorrelation in the as time-scale
Cross-correlation methods – RABITT, CRAB

- **Ultrafast Dynamics in Matter**

Photoionization of valence & innershell electrons
Dynamics of doubly excited states in atoms & molecules
Ultrafast dynamics in nano-structures and solids

● *Development of Shorter Wavelength Harmonic Sources*

- **Water-window (2.3 – 4.4 nm) and beyond**

1.6 keV (0.8 nm) harmonics from Ne driven by 3.8-um laser (VUT/JILA)

- **For sub-as or zeptosecond pulses**

For $\Delta t = 1$ as, $\Delta E \sim 600$ eV. $\Rightarrow$ HHG in the hard x-ray region
